Any donation from anything goes to charity to help save lives. Fisher in the Atlantic ocean-from North Carolina to the Caribbean-is best characterized by what is missing: snappers, groups, redbfish, lobsters and hosts of other species that once patrolled hundreds of miles of bay flow. But after a 21-year harvest moratorium, at least one species, the endangered Goliath group, made its comeback in those waters. As this species shows signs of recovery, there is mounting pressure to reopen the fish of groups- it is an important food fish as well as a favorite of sports fishermen. The management arena has become a political charge and a bag for better scientific knowledge, said Florida State University scientist Christopher C. Koenig in a statement. That could spell disaster, though; this gain is fragile. Similar situations were faced by cod and halibut fisheries at the Canadian Grand Banks in the early 1990s. Political managers doubled the proposed scientific capture limit, harvesting by 60% of the population in a season in 1992. By the end of the year, residents had collapsed. The moratorium, which took effect for 15 years, has just led to a nascent recovery. To avoid similar scenarios in the United States, NOAA launched a unique study that lists scientists, divers and fishermen to catch, tag and then release the coveted fish alive. The new data could give managers stronger scientific legs to manage the Goliath group, which can grow to 800 pounds more than 50 years, but it can also change its old and damaging dynamics. Those who catch fish-commercial and recreational fishermen, as well as divers-will also be among those most involved with consulting them. If successful, this concept can be applied to other species that are too much as a red cross, whose population has declined by about 90% since 1950.
